macOS Networking Problems

Introduction

This manual should serve as one of the primary tools for installation and operation of the Capture software. Capture Sweden's e-mail support and online web forum are available as important complements to this manual. <http://www.capturesweden.com>

Please visit our website for regular software updates and important product information. Also make sure to notify us if your e-mail address is changed, since e-mail is our primary communication channel.

Microsoft Windows

Capture is distributed with a Microsoft Installer (.msi) package available from our web site. Once you have downloaded the installation package, simply double click it to launch the installation.

macOS Installation

Capture is distributed as an ".app" package inside a .DMG (Disk Image) available from our website. Once downloaded, it can be run from any location. When run, the latest version of the library is automatically installed if necessary (hence it's possible to have multiple versions on a system, but they will all always use the latest version of the library).

The License Key File

Capture licenses are offered on a personal basis, which means that it is possible to use the key-file on more than one computer. As a result of that, it is also necessary to unlock the key-file on each computer, so that we can keep track of your Capture installations.

If you have purchased a Capture license and received a key file, you will need to install it. This is done from inside Capture; Open the Licensing dialog from the Tools menu and click on the Install key file button. Once you have chosen the license key and it has appeared in the window, choose either 'Automated unlock' or 'Manual unlock' if you are not connected to the Internet.

The manual unlocking process may take some time as it requires manual attention from the Capture Sweden staff, but we will help you as promptly as possible.

Library Updates

Library updates are continuously available on our website, <http://www.capturesweden.com>. If you have requested library additions, this is where you will download an updated library package when we have notified you of completion of your request. Each release of Capture also contains the latest available library package.

Support

Support to our customers is offered through e-mail and our online web forum at <http://www.capturesweden.com>. Under extraordinary circumstances we may also communicate with you over telephone, Skype or MSN. For fastest possible assistance, please make sure to e-mail us at the appropriate e-mail address. For questions regarding functionality or operation: support@capturesweden.com. For questions regarding the library or if you are missing fixtures: library@capturesweden.com.

Here are some things we will always ask you to do before helping you out:

- If you are a Microsoft Windows user, make sure that you have all the latest applicable service packs and hotfixes from Windows Update.
- If you are a Microsoft Windows user, check that you have the latest drivers for your computer components and your graphics card in particular.
- Check that you have installed the latest version of Capture and the latest library update.

Demo Version Limitations

The demo version of Capture comes with two (and no other) limitations:

- The Save function is disabled.
- The software will only run for 90 minutes.
- There are no limitations in terms of console or media server connectivity or the number of universes available for visualization.

Software Overview

On startup the Welcome dialog is shown with shortcuts to open recently opened project files and the Capture news feed. Once this has been closed, the main Capture interface remains.

The main components of the interface highlighted in the image are:

1. Main menu.
2. Design views (three in total).
3. Project window.
4. Navigator selection interface.
5. Navigator view interface.

Main Menu

The main menu is available at the top of the main window.

In the **File** menu you will find the basic commands for opening, saving and closing Capture project files. Note the variety of different options are available for opening older Capture project files.

The **Import Model** feature is used to open up other project files in parallel and allows you to copy items from other projects into the project you are working with (which is done using the arrow navigator button).

The **Import Data** feature allows you to import a variety of drawing formats from other programs, as well as specific project data such as fixture patch, weight, etc.

The **Import Project Content** feature allows you to import layers, filters, reports, plot styles and plots from another project.

The **Export Presentation** feature that allows you to create an executable file that will launch your project, which is embedded in the executable file, and show the Alpha view. Presentations cannot be used to edit project files, they merely serve as a viewing and presentation tool.

The **Export for Capture Nexum, Atlas, Argo** functions allow you to export your project to older versions of Capture.

The **Export focus sheets** feature creates a set of images, one per fixture (or as configured in the configuration dialog presented), giving you a view out through the aperture of the fixture. It requires you to pick a folder into which the images are placed.

In the **Edit** menu you will find access to the unlimited Undo and Redo commands.

The **Tools** menu gives you access to the **Options** window and the **Translation** window.

Design Views

Capture has three design views, **Alpha**, **Beta** and **Gamma**. These views can be configured to the users liking. Configuring a design view is done by clicking on the green list button as shown below.

Command	Description
Wireframe	Wireframe is the default view and works as a 3D CAD wireframe view whereby a user can orbit any object in 3D but it is only rendered in wireframe.
Plot	Replaces the Paper view from previous Capture versions. This view is used to make plots.
Live	Live 3D rendering view.
Custom	In Custom mode, you can configure your own look view with either wireframe/solid, perspective/orthographic etc.
Camera	Camera shows a list of preset camera positions for quick navigation, as well as the ability to launch one of the user made camera positions.
Store Camera	By positioning the camera to a user defined location, a user can then go to the Store camera option and choose a camera preset to store the current camera pose to.
Grid	Grid toggles the grid on/off for the selected view.
Widgets	Widgets (such as the camera) can be toggled on/off for the selected view.
Hidden Objects	Hidden objects can be toggled on/off for the selected view.
Project Information	Toggles the project information on/off for the selected view.
Fixture Information	Fixture information replaces the previous Live Information option from Capture Argo. It overlays fixtures with programming information like shutter and color mix status.
Quality Information	Toggles the FPS and quality info on/off for the selected view.
Save Image..	Save an image of the currently selected view.

Some view settings are not available in the navigator. Additional settings for each view are available in the **Design tab** of the **Project window**. With the **Views** category selected, each view has one column of properties appear on the right hand side.

The **Grid width** and **Grid height** properties determine the distance between grid lines.

The **Vertical field** of view property lets you control lens angle of the view's camera.

The **Aspect ratio** of a view can be set to follow 4:3 as well as 16:9.

The **Brightness**, **Exposure** and **Atmosphere** settings controls the look of the view when in Live mode. If you have enabled the "Simpler Graphics" option of Capture, **Brightness** and **Exposure** are replaced with **Fixture Lighting** and **Fixture Lighting Differentiation**.

DMX Control

It is possible to control a view using DMX. This is achieved by either manually assigning a Patch universe / channel or by dragging the view's camera from a design view to a channel in a universe view. The Patch mode option can be used to select the number of channels used by the camera.

Channel	Function	Channel	Function
1	X Coarse	10	Tilt Fine
2	X Fine	11	Pitch Coarse
3	Y Coarse	12	Pitch Fine
4	Y Fine	13	(unused)
5	Z Coarse	14	Ambient
6	Z Fine	15	Lighting
7	Pan Coarse	16	Atmosphere
8	Pan Fine	17	Layers Set ¹
9	Tilt Coarse	18	Scene ¹

¹ A total of 64 slots each occupying 4 DMX steps, ie. 0-3, 4-7, 8-11 and so on.

Project Window

The Project Window is the main information area in Capture. It hosts the properties for the selected items, additional settings for the Alpha, Beta and Gamma Views, settings for Layers and Filters, Scenes, Materials, Custom Gobo wheels, Custom Frame (color) lists, Reports Plot styles and Plots. Furthermore, the window is split into a navigation list down the side with the properties for whatever is selected from that list available on the right. Along the top are some tabs - Design, Fixtures, Universes, Media, Snapshots and Library. Generally speaking, to add an object of any type to a capture project, it needs to be dragged from the library tab to one of the design views. Objects can only currently be dragged into a wireframe or plot view.

Navigator

The Navigator is one of the main tools of capture. It is used for two primary functions - Navigation and Manipulation.

The navigation part of the Navigator is present in the bottom right corner of the Alpha, Beta and Gamma views. This Navigator is used to manipulate the view in terms of changing the camera viewing point and zoom within the view as well as accessing the view settings via the spanner button.

The First button, a curve with arrows, allows you to move around a view. Holding the Shift or Ctrl keys allows a different style of movement in the 3D views.

The second button is used to zoom in and out on the selected view. Holding the button and moving the mouse up or down will control the amount the camera is zoomed in or out.

The third button is used to access the settings for the selected view as we discussed earlier. Additional settings for each are available in the **Design tab** of the **Project window**.

Whenever you select any objects, within any of the Alpha, Beta or Gamma views within Capture; a second type navigator appears. When objects are selected, they appear red with a red grid around them that has some control buttons below it. This second type of navigator is used to assist in the manipulation of the objects.

Objects can be selected by clicking on them with the mouse. Use the Shift key to add objects to the selection and the Ctrl key to toggle individual object selection on and off. By click-dragging the mouse over a group of objects, you can select them all at a time. If you drag from the left to the right, the objects must lie completely within the region, but if you drag from the right to the left, it is enough for the objects to be partially inside the region in order to become selected.

Clicking and moving the mouse anywhere inside the Translation grip allows you to move objects around. This area is intentionally large so that it is easy to move items. While moving items, you can enable the ortho mode by pressing Shift key. Snapping in the sense of bringing items to a minimal distance is built in and activated during any translation, but is not triggered until after a short delay. When snapping is activate, the result of the snapping is illustrated with an alternate colour.

Clicking and moving the mouse inside a Distribution grip will allow you to spread out or bring together the selected objects over the given area in a proportional manner. The ortho mode is available here by using the Shift key as well. The Rotation anchor is used to rotate objects. It can be moved around to define the center of rotation and allows for both Individual rotation and Group rotation. Pressing the Shift key enables snapped rotation.

The first button is the selection menu button. It allows you to select or deselect everything, with the added "layer" option. Using the "layer" option will allow you to select or deselect everything but only in the current layer. Layers will be discussed in a later chapter.

The second button is the actions menu button. It displays a small list of possible operations relevant to the selected object(s). The list that appears is context sensitive, that is to say that selecting a Lighting Fixture will display different options in the list than that of a Truss. Each available option/command will be covered later in the relevant chapters.

The arrow button is used to drag objects out of one view to another. Using this button, the objects won't actually move per say. The button is used primarily for patching fixtures. Select multiple fixtures in the order you wish to patch them and use the drag button to drag them onto a universe in the project window or on an open universe window. This functionality will be covered later in the relevant section.

You may also use the arrow button to drag the object to a new location in the same window, thereby making a copy.

The button with a list is the Quick Summery button. Pressing it when you have objects selected presents a popup window about the selected objects displaying key data about them. This button reveals the fixture control pane and is only visible when at least one lighting fixture is selected and the view is in Live mode.

Smoke Settings

Since Capture Atlas, Smoke is no longer a global setting, but a placeable and modifiable element of your design. Typical applications include denser smoke on stage in an arena with thin haze or other localized fog situations such as heavy fog or fog behind a glass. Being able to limit smoke to the area around the stage helps avoid problems with beams shot into the audience over saturating the visualization. The Smoke element is in a new project by default (much like the camera object).

Smoke can also be patched to DMX control. It has 2 control channels, Density (1) and Variation (2). It can be patched by manually dragging the object using the select button into your chosen universe window (much like a fixture) or manual given an address once it is selected by changing its patch property in the Design tab.

Rendering Settings

The rendering settings (previously visualization settings, under software options) is a tab within the project window. Its properties control the rendering quality of the live design views.

The **Multiple Apertures visualization** option controls the rendering of multi-aperture (striplights, BB-7, multi-LED moving heads) beams. In simple mode, only a single beam is rendered using the fixtures average color. In realistic mode each aperture renders a beam of its own. In Automatic mode a single beam is rendered for the fixture when all apertures have the same color.

The **Beam Atmospheric Detail** option allows you to control the level of detail created by a beam passing through the smoke/haze in the atmosphere.

The **Beam shadow resolution** option allows you to lower the resolution of shadows created by beams.

The **Automatic Quality** option allows you to turn on/off the automatic quality functionality Capture uses. Having automatic quality turned on will allow capture to be more efficient while rendering more complex scenes by sacrificing quality to keep good performance.

The **Resolution Scaling** option allows you to render live visualization at a lower resolution than the screen.

The **Atmospheric Resolution** option controls the resolution of atmospheric visualization, (Smoke). The Beam

Atmospheric Details option allows you to control the level of detail created by a beam passing through the smoke/haze in the atmosphere. Higher levels of Beam Atmospheric Detail are relevant when using many

wide angle beams and/or shooting through scenery that intersects beams.

The **Beam Shadow Resolution** option allows you to increase the resolution of shadows created by beams when shooting over long distances or on/through scenery.

The **Spill Lighting** option enables the visualization of a beam contribution beyond a fixtures field angle.

The **Frosted Transparents** option allows you to disable the visualization of the frosted effect of transparent materials.

Software Options

The software options are available through the **Tools** menu **Options** command and are split in two categories.

General Options Tab

Here you can change the language of the user interface in Capture. By default it will follow the settings of your computer.

The **Ignore C: drive** options is important on Microsoft Windows machines that have their Windows installation on a drive other than C : \

Turning on the **Live updating** transformation option causes all simulation views to update at once when moving or rotating objects.

Locking layers is a useful way of preventing accidental modification of fixed items such as the house of your venue. The **Locked layers unselectable** option takes it one step further and prevents you from even selecting such items.

The **Show navigator on external selection** is a feature for users with controllers that are capable of selecting fixtures. Unless this option is enabled, fixtures selected from a controller will only highlight as red and not display the navigator with the command buttons.

Free-flight navigation is normally accessible using the Shift key when navigating but can be set as the default behaviour instead (in which case the Shift key can be used to access orbit navigation).

The size of the navigator's rotation anchor can be changed with the **Rotation anchor angle** and **Rotation anchor length** options. The rotation anchor snapping angle can be set with the **Rotation snap angle** option.

Connectivity Options Tab

This tab contains options for controller and media server connectivity. It can be important to set the Preferred network address on a machine with multiple network addresses, but unless you are connecting to older equipment it is not encouraged to enable the Compatible CITP mode as it may make it impossible to connect to newer equipment.

You may also alter the **incoming video format** for CITP communication.

By default, Art-Net, sACN (E1.31), Compulite VC, ETC Net 2, HippoMap (HMap3), Lan Box, Lasergraph DSP and PangolinLD are all set to **Automatic**. On rare occasions when a machine has more than one network adapter, it may be necessary to change **Automatic** to a specific IP address available under the relevant protocol.

Object Manipulation

Any physical thing in a Capture project file is an object, whether it be a Lighting Fixture, piece of stage deck, LED screen, table or chair - is irrelevant. They are all treated the same in respect to adding them to the project, moving them around, cloning (copying) them, deleting them and accessing their properties.

To explore more about object manipulation, start a new Capture Project. Do this by going to the main menu in the top left corner and pressing **New**.

Leave the Alpha and Beta views with their default settings. Change the Gamma view to the **Live** mode by clicking on the green list button and selecting Live. Your windows should look the same as the image below.

Adding Objects

Now we have a clean project file, we can proceed to add some objects to it.

To add an object to the project, we must first locate it from the Library. The **Library tab** in the **Project Window** is where all objects can be located. We want to add a stage floor.

Navigate to the Library, click on **Objects**, then again on **Forms**. Click on the **Box** form and drag it into either the **Alpha** or **Beta** view. Your project should look something like the image below.

We can now proceed to changing the properties of the box so that it looks more like a stage floor. You may select the box by simply clicking on it in any of the views. The red navigator will appear around the box. Press the red spanner button to present the options available for the box.

Click the **Properties** option. This will toggle the project window to the **Design** tab with the **Selected Items** section already active showing the properties for the box.

Change the box dimensions to a width of 12m, height of 0.1m and a depth of 8m. Your Properties should look like the image below.

The end result will be the box looking a lot more like a floor.

Now we have a stage floor in place we can proceed to add some more objects. We will add some truss in above the stage. Adding a piece of truss is done in the same way the box was added. Locate the desired piece in the library and drag it into either the Alpha or Beta view. For the sake of example, we will use a piece of truss from the **Generic** folder. Double click the **Truss** folder, double click again on the **Generic** folder, and again on **Box**. Choose the **Generic Rectangular Section** and drag it into one of the views.

The Truss is 2m wide. We know that the stage floor is 12m wide. We now want to add more 2m sections of truss to result in one long truss going from one side of the stage to the other. This can easily be done with the **Clone** feature.

Click on the truss piece to select it. Press the red spanner button to access the available options for the truss.

Click the **Clone** option, this will bring up the **Clone** window. Set the **X Offset** to **2m** and set the number of clones to **5**. This will then add sections of 2m truss right across our 12m wide stage evenly.

Currently, they still act as 6 separate pieces of truss. Select the pieces and press the red spanner button again. Choose the **Group** option and now the 6 sections are grouped together. They can now be moved and manipulated all as one.

Navigator commands

The navigator's actions menu contains a number of commands that can be used to manipulate the currently selected objects.

Transform

This command allows you to move or rotate by an exact distance or amount of degrees. Use the green navigator cube to guide you with the X, Y and Z directions in the current view. Note that the rotation angle takes the placement of the rotation anchor into account and always performs a Group rotation.

Align

The Align option allows you to select a group of objects and quickly align them along a specific axis very quickly. Whatever align function is used is always relevant to the design view you are using it in. The options available are displayed to the right.

Spread Even

The Spread Even function allows you to select a group of objects or fixtures and spread them evenly along a vertical or horizontal axis very quickly. It is extremely useful for making lines of objects very quickly.

Clone

This command allows you to create one or more copies of the object or group of objects you have selected. Use the green navigator cube to guide you with the X, Y and Z directions in the current view. The offset values are applied incrementally which means that if you specify two copies with an offset of 2m, the first copy will be created 2m away from the original and the second copy will be created 4m away from the original etc. Note that the rotation angle takes the placement of the rotation anchor into account.

For instance you can create a circle of ten boxes by selecting a box, moving the rotation anchor of the circle, choosing the Clone command, entering an angle of 36 degrees (a full circle of 360 degrees split in ten objects) and 9 copies (since one box already exists, the result will be 10 boxes).

Sequential Unit

This command allows you to set the Unit property of the selected objects in a consecutive manner. You may specify a Prefix as well as a Postfix to the numbering. The Start property defines the first number of the range. The Overlap property allows you to create series such as 1, 1, 2, 2, 3, 3 and the Gap property allows you to create series such as 1, 3, 5, 7. Notice that if you select objects manually one by one, this defines the order for the numbering. However, if you select them by dragging the mouse over the objects, the order of the objects undefined.

Sequential Circuit

Sequential circuit essentially works just like sequential uniting – except that you assign circuit numbers to the Channel property of fixtures. You may specify a Prefix as well as a Postfix to the numbering.

Sequential Patch

This command allows you to sequentially patch fixtures. The order in which you select the fixtures will be the order they are applied to the patch. You may choose the universe and start address by entering the address as Universe.Address. For example, entering 2.1 would have the fixtures start at channel 1 on universe 2. You also have the option of leaving a gap between fixtures if you wish.

Sequential Channel

Sequential channel essentially works just like sequential uniting – except that you assign fixture numbers to the Channel property of fixtures. Since it is a number and not text, you are not allowed to specify a prefix or postfix.

Fixtures

Fixtures Overview

Fixtures are handled in pretty much the same way as other objects. To add a fixture, it needs to be dragged from the library to one of the wireframe design views. Fixtures can be cloned, moved, rotated and deleted the same as any other object.

In this example, we add a single Mac 700 profile from the library. We then clone it so that we end up with one Mac 700 per meter of the truss.

Clone the Mac 700 Profile 11 times so the 12m truss has 1 Mac 700 every meter. The Mac 700's will then span the truss equally.

Now that we have added the Mac 700's. They need to be patched. There are two ways of patching fixtures in Capture. You can select the fixtures you wish to patch, in the order you want them patched, and from the red spanner (options) menu, you can select "Sequential Patch". The sequential patch window will appear giving you the options of "Start Address", which is formatted by double clicking the option and entering Universe.Address. For examples entering 2.1 would patch the fixtures to Universe 2, Address 1. You may also enter a "Channels between fixtures" number, this is essentially an offset tool.

The second option is to drag the fixtures to a start address within a universe window. First, open one of the project universes by clicking on the "Edit.." button in the "Universes" tab of the Project Window. Then select the fixtures in the order you wish to patch them, click and hold the drag button and drag them to a start address in the open universe window.

DMX Universes

Once fixtures are patched onto Captures internal universes, you can link those internal universes to external universes that are coming into Capture via protocols like Art-Net or sACN. Very little user intervention is required with most of these protocols - Capture will accept most of them in a "Plug & Play" kind of manner.

Universes are managed in the *Universes* tab of the *Project window*. The left hand side shows the universes of your project and the right hand offers a preview of the selected universe.

Capture automatically links external universes to internal universes, but also offers you the option of overriding the setup. To do this, double click on the *External universe* column property of a universe and choose the external universe you would rather use.

The *Patch base* property lets you choose the numerical location of a universe in relation to the other universes, independent of its name.

In a theatrical environment it may be more convenient to work with a contiguous range of channel numbers (for instance 1 – 2048). This can be achieved by setting the *Patch style* property to *Contiguous*.

Fixture Settings

All fixture settings are available in the *Design* tab of the *Project Window*, as illustrated on the right hand side. The settings are divided in several categories. It is possible to select multiple fixtures at once to change a setting for all selected fixtures simultaneously.

Swapping Fixtures

Swapping fixtures in Capture is very easy. To replace fixtures, select the “old” fixtures first, then locate your “new” fixture from the library. Simply drag the new fixture onto one of the selected “old” fixtures. The selection will go a purple color, once you see the purple color, release the mouse button and the fixtures will have been swapped.

Custom Gobos

Custom gobos can be created by right clicking on the Gobos branch in the Design tab. Once you have given the gobo a name you can choose an image for it. Use a square image, up to 256 by 256 pixels in size.

Finally drag and drop the gobo onto any fixture with a gobo slot to add it to the fixture. If you have selected multiple fixtures as you do this, the gobo will be added to all of them.

Gobos (and filters) can be removed from fixtures using the actions menu button.

Custom Gobo and Color Wheels

Changing Gobo/Color frames in intelligent fixtures is very easy, simply open the current wheel via the fixture properties, double clicking on one of the current color/gobo slots in the properties opens the wheel, then drag a new color or gobo from the library to a slot on the wheel and the fixture is automatically updated.

The Fixtures Tab

The Fixtures Tab is part of the Project Window and shows all fixtures in the show and subset of their settings. The Fixtures Tab can be navigated and edited as a spreadsheet using the arrow and Enter/Return keys. Multiple row selection is also possible using the Shift and Ctrl/Cmd keys and useful when dragging and dropping fixtures from the Fixtures Tab.

[New project]

Design Fixtures Universes Media Snapshots Library

Project fixtures

Unit	Channel	Name	Circuit	Patch [^]	Mode	Optics	Weight	Slot frames	Focus
0		MAC 700 Profile		A.1	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.24	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.47	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.70	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.93	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.116	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.139	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.162	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.185	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.208	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.231	16-bit Basic ...	Standard Lens, 1...	34,5kg		
0		MAC 700 Profile		A.254	16-bit Basic ...	Standard Lens, 1...	34,5kg		

The *Fixtures tab* can be arranged in a number of ways. By default, the tab shows all fixtures currently in the project. It can be filtered by using the search function in the top right corner. It can also be filtered by clicking a column header to organize the data in ascending (or descending) order for that property. For example, in the image below, the window is filtered to show the source four fixtures ascending in patch data. The arrow in the Patch property column header denotes that the sheet is arranged showing patch data in ascending order. Clicking the Patch column header for a second time would toggle it into descending order.

Materials

Using Materials

Materials offer a way of applying a static image or video to an object. The best way to use a material is to think of it as an example of what your object is going to look like. They are useful to make objects appear as different things, for example mapping a picture of a bricks to a thin box, making it appear as a wall.

The library contains a selection of materials which can be applied to objects by dragging and dropping them from the library on to the object. To apply the same material to many objects, you can select the objects first and then drag and drop the material. The image and colour of the material is combined with the colour of the object that the material is applied to. Hence, if the object's colour is set to black, the material will appear black.

You can create your own materials in the *Design tab* of the *Project window*, under the *Materials category*. You can then apply either an image from a file, a video on the local hard drive or streaming video source from a connected media server. To apply your own materials to objects, drag and drop them from the Materials branch rather than the Library tab.

In this example, we will look at using Materials to change the appearance of a thin box. First, make a new material in the project window.

In the material properties, available on the right when the material is selected, you may choose an image or video source. Double click on the image option and choose an image from the local hard drive. In this instance, the image will be a picture of some bricks. Once you have chosen the image, drag the material from the project window to the object you wish to map it to.

Mapping Materials

Once you have applied a material to an object, you may wish to map the material. Mapping a material consists of using the navigator to resize it, rotate it or fill the object space with the material, the latter is referred to as “Map to Extents”.

Moving and resizing the material with the navigator is done in the same manner as other objects. You may Map a material to multiple objects at the same time. Simply select all to the objects and drag the material to them, select the “Map Material” mode and map the material to your liking.

Material Properties

The **Color** property defines the base color of the material. Capture utilizes the Physical Based Rendering (PBR) material model in which absolute white or black should normally be avoided.

The **Texture image**, **Texture generator** and **Texture media** choices are mutually exclusive and allow you to apply a texture to the material. This texture is combined with the base color and unless you wish to tint the texture with a color, the **Color** property is then best set to pure white.

Use the **Texture Width** and **Texture Height** properties to define the physical real-world dimensions of the image, generator or media texture applied. These dimensions define the size of the image regardless of the object it is applied to.

The **Smoothness** property defines how rough or smooth a surface is on a microscopic level. A material such as concrete would have a much lower smoothness value than for instance varnished wood.

The **Metallic** property allows you to mimic metallic looking finishes for metal items such as a car or steel beam. This should normally only be set to either 0% or 100%.

The **Luminance** property allows you to create materials that simulate light emitting surfaces such as flat screens or LED panels.

Transparency allows you to set transparency for an object so to act like glass or gauze. This property works together with the **Tint** which determines whether items behind the object assume the colour of the object itself, as is the case with glass but not gauze. Finally **Frost** allows you to give transparent objects a frosted effect.

Texture Generators

Texture generators are a kind of crossover between media servers and static image textures. Texture generators produce a matrix image where the cell colours are controlled by DMX. This can be used for a number of effects, for example dimming a luminous object or simulating an RGB LED tape.

Texture generators support two DMX modes - **Dimmer** and **RGB**. In Dimmer mode each cell is coloured from black to white, based on a single DMX value. In RGB mode each cell's colour is controlled by three DMX channels.

When patching a texture generator the number of channels required is determined by the DMX mode chosen and the number of **rows** and **columns** configured. I.e. a 3 by 3 matrix in RGB mode requires $3 \times 3 \times 3 = 27$ DMX channels.

Media Fixtures

Video Projectors and Digital Lights

Capture supports a large library of Media Fixtures such as Video Projectors and Digital Lights. Adding a Media Fixture to a Capture Project is the same as anything else - drag it from the library into one of wireframe views.

With Projectors and Digital Lights, they need a video source for any output to be visible. Much like LED Screens, the video source may be an internal video player were by you choose a video file on the computer and play that. Alternatively you may also choose a video source from an external Media Server via CITP for the video source of a Projector.

In this instance we will just use a file on the computer and look at CITP sources in a later chapter.

Add a video projector to the project by dragging it from the library to one of the wireframe design views. You can select a non specific projector from the "Generic" section of Media Fixtures in the library. Add a box, and change its properties so that it looks like a video screen. Position the projector so it is pointing at the screen. A quick way to focus a projector (or any type of fixture) is to right click on the surface you wish to focus it on. In this case, its the screen on stage.

The projector will display a test image when it is turned on but not being assigned an image or media player.

Now, to play video from the projector, you can create a video player within capture. Simply, go to the **Media tab** in the **Project window** and press the **Add** button in the top right corner and name the video player "Projector Video". Press the **Add Video** button and choose a video file from the local hard drive. You may select multiple videos as well as image files if you wish. Once you have selected the video you wish to play through the projector, press the play button next to it so the video is playing.

Finally select the video projector and access its properties in the **Design tab**. Double click on the **Media** property and choose the video player you had just created.

Video Players

As discussed in the previous section, you can use an internal Video Player to play videos or images on Video Projectors in Capture. The Video Player can be controlled by DMX if desired. The Patch property of the Video Player can be access by clicking "Settings.." for the desired Video Player in the Media tab.

Channel 1		Channel 2	
0-7	Pause	0-31	Playlist entry 1
8-15	Play	32-63	Playlist entry 2
16-23	Replay (Play again from the start)	(similarly)	(playlist entries 3 through 7)
24-31	Stop	248-255	Playlist entry 8

Using CITP Media Sources

Capture supports connecting to Media Servers using the CITP communication protocol. This makes it possible to receive streaming video from a Media Server and apply it to objects like a material. You can view all connected Media Servers in the **Video tab** in the **Project window**.

To apply a streaming video to an object, you must first create a material, select the desired video source, set up the dimensions of the material and then apply the material to the objects. Alternatively you may omit setting up the material dimensions and simply map the material using the material mapping functionality discussed earlier.

Little to zero configuration should be required with CITP. Ensure that the Capture machine and the Media Server are operating in the same range of IP addresses and subnet. If the Capture machine has multiple network adapters, it may be necessary to manually select the adapter you will be using for CITP information. This can be done in the **Connectivity Tab** of the **Options menu**.

Controller and Media Server Connectivity

	macOS	Windows
Art-Net	Yes	Yes
Avolites ACDI		Yes
CITP	Yes	Yes
Compulite VC	Yes	Yes
EntTec DMX USB Pro Mk1 & Mk2	Yes	Yes
ETC Net 2	Yes	Yes
Green Hippo HMap 3	Yes	Yes
High End Hog 3 & 4	Yes	Yes
Kinesys K2	Yes	Yes
LaserAnimation & Pangolin	Yes	Yes
MA Net 2 ¹		Yes
Streaming ACN	Yes	Yes

¹ Requires MA software version 2.9. Requires manual activation; right click in the External universes list of the Universes tab to open the MA-Net configuration dialog.

NDI Video Sources

Capture supports receiving video from NewTek NDI (<http://www.newtek.com/ndi.html>) video sources. This makes it possible to receive streaming video from a multitude of both software and hardware solutions. There are also some useful tools for desktop streaming and tests available from the NDI web page of NewTek. Capture lists all NDI sources it finds in the Video tab in the Project Window.

To apply streaming video to an object, follow the same procedure as with CITP Media Sources, described in the previous section.

No configuration is required for NDI, but it is possible to specify one or several NDI groups to limit NDI reception to in the Connectivity Tab of the Options menu. If the Capture machine has multiple network adapters, it may also be necessary to manually select the adapter you wish to use.

LED Screens

Using LED Screens

Capture is not only capable of 3D rendering for Lighting Fixtures, but also a wide range of LED Screens too.

Adding an LED screen to a project, is the same as adding a fixture or object. LED Screens can be found under the Fixtures category of the library. Locate the particular model you require from the library and drag it into one of the wireframe design views. Use the clone function to clone the LED panel however many times is required to create the screen size you desire. Once You have added in an LED screen of the desired size. Mapping video to the screen is done with the use of **Materials** and **Video Players**.

Materials are images or videos you add to an object in capture. Video Players can either be an internal video player were by you choose a video file on the computer and play that. Or you may also choose a video source from an external Media Server via CITP for the video source of a material. In this instance we will just use a file on the computer and look at CITP sources in a later chapter.

Add an LED Panel to the project by dragging it from the library to one of the wireframe design views. Clone the panel so you have a suitable size of LED Screen. Your project should look similar to this.

Now, to play video on the LED Screen, you must make a video player within capture. Simply, go to the **Media tab** in the **Project window** and press the **Add button** in the top right corner and name the Video Player - "LED Screen Video". Press the **Add Video button** and choose a video file from the local hard drive. You may select multiple videos if you wish. Once you have selected the video you wish to play on the screen, press the play button next to it so the video is playing. In the **Design tab**, select the **Materials category** and click the **Add button**.

Once you have created the material, you need to link the material to the video player. Do this by selecting the video player from the "Media" option within the material properties.

Once the Material has been assigned to the video player, drag the material from the project window to the LED Screen in one of the design views. Press the red spanner button and choose the "Map Material" option. Then select the "Map to extents" option, this will set the material to fill the whole screen.

The result will be the LED Screen receiving evenly mapped video across the array from the Video Player.

Layers and Filters

Using Layers

Both layers and filters are managed in the Design tab of the Project window. Layers are useful to select & group many objects of a similar nature. Filters are essentially just groups of layers and universes. For example having a layer for "All Moving Lights", "All Generics" and "All LED" could be useful. Then they could belong to the filter - "All Fixtures". Layers and filters are very useful for managing project files with large amounts of objects & fixtures in.

Objects in a layer with the Locked property set cannot be modified. When the Include in reports property is unchecked, objects in that layer will not appear on reports. Live information and Fixture simulation can also be turned on and off on a per-layer basis in the same fashion. Filters are used to define sets of layers to be visible in design views and plots. They serve as layer filters and it is useful to note that you may work with different filters in different views if you wish.

When a design view is patched to a universe it is possible to choose the design view's filter via DMX. However, this requires setting up the DMX control slot property of each layer that you wish to be able to choose. There are 64 slots available and they are identified with the numbers 1 through 64. A value of 0 means that it is not possible to select via DMX.

Please note, that hiding layers does not affect light and shows because the objects are still considered physically present. So in order to achieve something like this, you must use Scenes.

Adding fixtures or objects to a layer can be done in one of two ways, you may either drag the layer from the project window to the selected objects or you may select the objects and double click the "Layer" property in the properties and select the layer there. Adding fixtures to an existing layer is done in the same manner.

Using Filters

As already discussed, filters are essentially just groups of layers and universes. As per our previous example, having a layer for "All Moving Lights", "All Generics" and "All LED" could be useful. They could then belong to the filter - "All Fixtures".

Adding filters is done in the same way as layers. Click on the Add button in the Filters category of the Design tab and name the filter. Once the filter has been created, in the right hand section of the window, a list will appear showing all the layers and universes. You can use the check boxes to control which layers and universes belong to the filter you created.

Scenes

Using Scenes

Working with scenes allows you to modify the position and visibility of objects in different parts of a performance. If you wish to do this, it is important to set the Include in scenes property of the objects that wish to have dynamic positioning/visibility (this is important because many items such as the rig, truss and house will usually not be part of what can be moved during a show and keeping them out of scenes prevents you from making serious mistakes). Scenes are not stored or recalled – you are always working in one scene at a time and you can safely switch back and forth between scenes without risking loss of any position information. Scenes are most useful in a Theatre environment where you have one set of scenery for Act one and another set of scenery for Act two. By default there is already one scene in any project file - the "Default Scene". To make more Scenes, right click on the scene node in the project window. Select "Add Scene" and name the scene accordingly.

Once you have made a second scene, we can proceed to make a scenery change. Add some scenery and position it as per your liking. Select all of the scenery, in the properties, locate the "Include in scenes" property and set it to "Yes". Now double click your second scene (or right click on it and select "Go to scene"). Now we are in the second scene, move the scenery to a new location. Now switching between the two scenes moves the scenery between the two locations.

Plots and Paperwork

Plots

The plots functionality in Capture allows users to create paperwork of lighting plots featuring key information about the lighting rig. A plot can be viewed and edited in any design view that is orientated to the top view & plot mode, as shown below.

Plot Options

Other than Fixture symbols, there are many other symbols that can appear on plots. The interactive image below shows examples of the available plot symbols. Symbols such as Sightlines, Fans, Fog Machines, Rigging Points etc may all be dragged into the project from the library just like other items. If you are unhappy with the default symbol for a fixture, you may drag a different symbol from the library to the selected fixture.

Item	Description
1	Optical information
2	Annotation
3	Focus information
4	Patch & circuit information
5	Colour filter information
6	Rigging point

Fixture Properties with Plots

When fixtures are selected, there are some plot specific properties that are useful to know about.

Symbol will control which symbol is used on the plot for the selected fixture.

Symbol Usage will control which views the symbol actually appears in.

Direction snap is set to 30 degrees by default, this property controls the direction the fixture is facing on the plot.

Color by filer will set the fixture color to match the gel filter it has.

Focus is the property that allows text to be placed in front of the fixture to indicate where that fixture is focused. I.e, drums.

Show Optics is the property that controls whether or not the plot displays the optical information of the fixture.

Show Wattage is the property that controls whether or not the plot displays the wattage information of the fixture.

Plot Styles

With Capture Argo, there is now an option to create styles for use with specific plots later. There are multiple properties that can be included in a style, which can toggle on and off.

Exporting Plots

Once a plot has been made in a paper design view, it can then be exported for print. To do this, create a new Plot by right clicking on "Plots" in the Project Window and clicking "New". Multiple Plots can be added in this manner. Adding multiple plots to the same project file is very useful for creating tidy plots for only certain parts of a rig. Each Plot can be setup to show only certain layers based on the filter you select for the view.

Once you have added a plot in the Project Window. Double click on it to open it. The paper settings can be changed in "Page Setup".

Right clicking on the plot will allow you to add a view to the plot as shown in the image below. You may also add Headers, Images, Text, Layer Keys and Symbol Keys in the same manner as adding a view.

Scale and move the plot to suit the paper.

Model Import

Using the Import Model Tool

The Import Model feature is used to import models from other file formats as well as importing content from other project files. It opens these files in parallel and allows you to copy items into the project you are working with by using the arrow navigator button.

When opening older project files, a window may appear telling you that some fixtures have been updated since the project you are trying to import from. Its good practice to hit "Update" so the new project gets the same version of fixtures as in the current library.

When you drag object into your project you have the option of placing them where you put the mouse pointer or at their original position. Once you have finished, simply close the file you were importing from.

When importing models from other file formats attempts to preserve Drawing block name and Drawing name information. This information can later be useful when replacing imported objects with library fixtures, either manually or using the Import Data feature.

Supported Model File Formats

Capture is able to import drawing information from other softwares using the file formats described below.

Autodesk DXF and DWG (.dxf and .dwg)

The DXF format is a relatively simple text based format useful to transfer smaller models and drawings of simple nature. The more complex DWG format can contain more complex information such as solids and materials.

Both the DXF and DWG formats stand out in the fact that they do not enforce a model object hierarchy – a drawing could consist of loosely scattered polygons and lines only. As this is a problem for Capture, all drawing content that does not belong to a "block" will be grouped by layer, material and solids to single objects in Capture. In order for textures to import, the texture image file must located at either the same path as on the computer on which the DXF or DWG was saved, or in the same folder as the DXF or DWG file being imported.

Block definition names are used as the Drawing block name, however the name of block definitions that only reference other blocks is also used as the Drawing name.

Cinema 4D (.c4d)

This is the native format of Maxon's Cinema 4D 3D package.

In order for Capture to be able to import model data from a C4D files it must either have been saved with the Cinema 4D preferences setting Files / Save Polygons for Melange set or using the Save Project for Melange.. function.

All objects in the scene graph are imported, but the tree as such is not preserved in any way. Only flat and UVW texture projections are supported.

Object names are used as the **Drawing name** and the name of the object referenced by an instance object is used as the **Drawing block name**.

Cinema 4D Hantmade Stage Plugin Support

When importing Cinema 4D files, Capture recognized Hantmade Stage fixtures and imports them as single objects. If a Capture fixture identity has been set a fixture's Capture export settings, the fixture is automatically replaced with a fixture from Capture's library.

Sketchup (.skp)

This is the native format of Trimble's Sketchup make and Sketchup Pro software packages.

While Sketchup supports double-sided materials Capture does not and will favor the front material over the back material. Capture will also preserve block and group transformations (useful for replace fixture operations) as long as no lines or surfaces in the group have been subject to mirroring.

Group and component names are used as the Drawing name and component definition names are used as the Drawing block name.

WaveFront (.obj)

This file format was developed by Wavefront Technologies for its Advanced Visualizer animation package in the 1980s. It is a simple and text based, yet very competent file format.

As with the 3DS format, OBJ files do not have material textures embedded. Instead they are loosely packaged alongside the OBJ file, typically in a separate folder.

Group names are used as the **Drawing name**.

3D Studio (.3ds)

This file format was the native format for the early versions of 3D Studio, a very popular 3D modeling software. It is rich in material settings and information required to produce very realistic models. Capture successfully handles most of the information in a 3DS file, however some of the more advanced material properties are not supported. 3DS textures are not embedded inside the 3DS file but loosely packaged, typically in a folder alongside the 3DS file itself. Be careful to take this into account when sending and receiving 3DS files! There is a rich amount of 3DS files available on the internet. However, many of these have been converted from other formats using automatic conversion tools of questionable quality.

Fixture Data Import and Export

Using the Import Fixture Data Tool

The Import Fixture Data tool can be found in the File menu and allows you to import a CSV text file containing fixture information which can be used either to add new fixtures to or update existing fixtures in your project.

CSV files are text files with information structured in a spreadsheet-like manner using (typically) commas as column dividers and linebreaks as row dividers. Because they are text files they can be opened and modified in text editors such as TextEdit or Notepad, but they are more typically produced and consumed by spreadsheet applications such as Numbers or Excel.

Capture attempts to configure itself automatically based on the headers Capture uses itself when using the Export Fixture Data tool, but also based on headers produced by other popular softwares. However, because ultimately any columns may be present in a CSV file it may be necessary to manually map some columns from the CSV file to Capture fixture properties. This is done in the File column mapping section.

In order for Capture to know whether to update an existing fixture or add a new fixture it is also necessary to select a property by which to uniquely identify fixtures. This is done with the Identify fixture by dropdown choice.

When Capture finds fixtures in the data file that do not exist in your project it can add new fixtures based on the information in the file. How to determine the type of fixture to add is decided by the column selected for the Fixture property of the New fixtures subsection.

Optionally, Capture can also replace imported objects in your project file with new fixtures. This behaviour is enabled by selecting a column for the Drawing name property of the New fixtures subsection. Capture then uses the Drawing name property of imported objects with the selected column of the data file to find matches. It is possible to choose whether the match needs to be exact or only partial using the Drawing name matching property.

Using the Export Fixture Data Tool

The Fixture Data Export tool in the File menu can be used to export CSV data files as well as grandMA 2 and Hog 4 XML patch files of the fixtures in the project and their associated data.

Exported CSV files can be opened in any text editors such as TextEdit or Notepad as well as spreadsheet software such as Numbers and Excel. Exported XML files can also be inspected in text editors even though they are only intended to be imported in the grandMA 2 and Hog 4 consoles.

To export, go to the "File" menu, select "Export Fixture Data.." and specify the desired location and name of the exported file. Following this some exporting options are available as well as the ability to change the exported file format.

Exporting to grandMA 2

When exporting to grandMA 2, a number of layer schemes are available:

- **Project layers** creates one MA layer for each Capture project layer with exported fixtures.

- **Fixture types** creates an MA layer for each type of fixture exported.
- **Single** creates one MA layer which contains all fixtures exported.

On export a dialog is also shown where it is possible to specify the manufacturer, product name and fixture numbers of each fixture type exported. If left as is, the fixture types can be assigned in grandMA 2 after import, but if you wish to avoid this step (and have already imported all required fixture types in your grandMA 2 show), then use these fields to set up the matching information.

Exporting to Hog 4

On export to Hog 4 it is important for the exported file to contain the exact same manufacturer and product names as in the Hog 4 fixture library as otherwise fixture will be skipped on import.

On export an additional dialog is shown where you can adjust the manufacturer and product names exported for each fixture. Crosscheck these with the names of the fixtures available in your fixture library or use it to change fixture types on export, for instance in order to swap fixtures for desk channels.

Importing exported fixture data in grandMA 2 onPC

First copy the exported MA 2 XML file to *C:\ProgramData\MA Lighting Technologies\grandma\gma2_V_x.x.x\fixture_layers*. Then, on the command line, enter the following commands, assuming the name of the exported file was *exported_file.xml*:

1. cd EditSetup
2. cd Layers
3. import exported_file.xml at 1
4. cd /

Motion Controllers

Using DMX Motion Controllers

Capture has the functionality to allow incoming DMX channels to be mapped to control the height and rotation of objects. In these examples, we are going to look at moving truss around with DMX. The functionality is not limited to trusses only, it can be used with most objects and forms within Capture.

There are two types of DMX Motion Controllers in Capture. The DMX Mover and the DMX Rotator.

The DMX Motion Controllers are added to a project like any other object in Capture - by dragging them from the Library into one of the design views. Its best to look at the controllers like lighting fixtures, they are fixtures in the project. Its good practice to place the movers near to the object they are controlling for ease of identification and manipulation, but they may be hidden from view if required.

The DMX Mover, pictured to the right, has two blobs at each end of the range. The thicker blob indicates the default starting point of the object the Mover is attached to. The thinner blob indicates the lowest point to Mover operates to.

The DMX Rotator, pictured to the right, is shown here as it is seen in the "Orthographic Front" design view. The thick blob in the middle of the circle indicates the central rotation point that the object will rotate around. The line protruding from the centre of the circle from the blob is the default starting point. The circle itself indicates the range in which the Rotator can operate. In this case, it is a full circle as the Rotator has a range of 360 degrees.

Adding a DMX Mover

As we discussed, the first type of DMX Motion Controller is the DMX Mover.

The DMX Mover can move an object across a predefined range on the X Y Z axis. The mover can also be configured to operate on only one axis, for example Y, so that the object it is attached too will only move up and down.

Drag the DMX Mover into the project from the library. It can be found under "Motion Controllers". Position it near to the truss it will be linked with, this will make it easier to manage projects with multiple movers.

Select the mover and access its properties in the Project Window.

Give the mover a name, using the "Unit" field. Then configure its properties to match the ranges in which you want to mover to operate. In this case, the X and Z range will be 0 and the Y range will be -5.8m as we only want the mover to move the truss up and down. 5.8m is the distance between the truss and the floor.

Select the Truss and the Fixtures you wish to move and select the DMX Mover from the "Motion Fixture" property in the Project Window.

The DMX Mover can now be selected and manipulated in the Live view just like any other fixture.

Adding a DMX Rotator

The second DMX Motion Controller is the DMX Rotator. The Rotator can be used to rotate an object around on an axis and within a specific range on that axis.

Now we add in a DMX Rotator and link the truss to it. We then go on to link the Rotator to the DMX Mover we created earlier. We call this “Chaining”. Once chained together it means that we can select both the Mover & Rotator and have individual control over both. The initial placement of the Rotator is of great importance. Wherever the Rotator is placed will be the point on which the rotation occurs. For example, we place the Rotator in the middle of the truss so that the truss Rotates around that point. Drag the DMX Rotator into the project from the library. It can be found under “Motion Controllers”.

Select the Truss and the Fixtures you wish to rotate and select the DMX Rotator from the “Motion Fixture” property in the Project Window.

Now, select the DMX Rotator and in the “Motion Fixture” property, assign the Rotator to the DMX Mover. This “Chains” the two motion controllers together so that when we select both, the truss can be moved up and down and rotated at the same time.

The DMX Mover & Rotator can now be selected and manipulated in the Live view just like any other fixtures.

Patching a DMX Motion Controller

Because a DMX Motion Controller is treated just like a Fixture in Capture, it is patched in the same manner. You can manually enter its patch and mode data in the properties tab of the Project Window, or you may use the drag function to drag it onto the start channel of a particular universe. The patch property for the controller can be found under “Control” in the selected items section of the Design tab.

Snapshots and Video Rendering

Snapshots

The still snapshots makes it possible to quickly move between key lighting looks while making design changes, even if no console is present. You can create high resolution renders at any point, watermarked with your logo and project information. Record movie snapshots including DMX, media and motion of parts of your show for offline playback. Export stand-alone 'Presentation' files that allow playback of all your snapshots while in an interactive environment - on any computer! Or if you prefer, render a high quality full-frame rate video file of your movie snapshots. To record a snapshot, simply press either the Record Still or Record Movie button in the snapshots tab of the Project Window. When recording a movie look, an extra dialog box will appear that allows you to set the FPS and start/stop. Snapshots can be played back by pressing the Play/Stop buttons the appear to the left of the Snapshot in the Snapshot tab.

Advanced File Menu Functions

Special Import Workflows

VectorWorks

It is possible to import a design from VectorWorks including both stage design / geometry model and fixtures. The workflow requires access to VectorWorks.

First export a DWG file from VectorWorks which will contain the stage model as well as the model of the fixtures. Then also export an "Instrument Data" file using the "All" setting which will contain all information about the fixtures in the DWG file such as their fixture type(s) and patch.

In Capture, first use the Model Import tool to import the DWG file. At this point you will see VectorWork's 3D models of the fixtures and be able to select them, but not operate them as Capture does not yet understand that they are fixtures.

Finally use the Data Import tool to import the "Instrument Data" file previously exported. Once you have identified the fixture types of the file you will see the previously inanimate fixture models exchange for regular Capture fixtures, fully functional and with relevant information such as patch and notes transferred from VectorWorks.

Using the Export Focus Sheets Tool

The export focus sheets feature creates a set of images, one per fixture (or as configured in the configuration dialog presented), giving you a view out through the aperture of the fixture. It requires you to pick a folder into which the images are placed. The feature relies on having assigned "units" within the project, this can be done by using the "Sequential Unit" feature discussed earlier in the manual. Fixtures that do not have a unit number assigned will not be exported. You may create focus sheets based on layer sets, this allows for you to only export certain groups of fixtures. Simply make a layer with only the fixtures you wish to export, assign it to a filter, then select that filter in the export options window. If you only want to export focus sheets for the selected fixtures, set the "selected fixtures only" option to "Yes" in the export options.

Update Library

Occasionally, it is necessary to update the Fixture Library in between main software releases. This can be accomplished by going to the downloads page of the Capture website <http://www.capturesweden.com/Download/Standard.aspx> and downloading the latest Library file.

Note that the library file has a .c2z file extension. In Capture, go to the Tools menu. Select "Library Update" and choose the .c2z file you downloaded. Capture will install this latest library file and then prompt you to restart.

Troubleshooting

Should you run into any problems, do not hesitate to contact us at support@capturesweden.com.

Graphics and Video Driver Related Problems

Capture is a professional visualization software and has high demands on video cards and their drivers. In case of problems, the following may help:

- Updating the video driver
- Trying different screen configurations (primary screen, number of screens and maybe even screen resolutions)
- Updating your operating system
- Upgrading your graphics card

IP Networking Problems

If your computer is set up with multiple IP addresses, Capture will ask you to select one of them as the primary. This is important for many protocols and the option required to set is available in the Options dialog from the Tools menu.

Windows Networking Problems

If your computer is not connected to a network at all but you wish to work with software based controllers on the same computer it may be necessary to install the Microsoft Loopback adapter. The process is simple and described at <http://support.microsoft.com/kb/839013>.

macOS Networking Problems

If you are experiencing problems connecting Capture to your console or offline software under macOS, it may be worth turning on an off the macOS firewall. This is done in the System Preferences, under Security & Privacy.
